THE HASTINGS ALGORITHM AT FIFTY

Paper discussion

Ola Rasmussen & Khanh Truong

February 12, 2024

Contents

Summary

1. INTRODUCTION

2. SOME KEY HISTORICAL DEVELOPMENTS

Summary

- ▶ 1970, W. K. Hastings, Markov chain algorithms, sampling
- ▶ Stationary distribution is target distribution
- ▶ Hastings improved Metropolis, allowed asymmetry
- ▶ Bayesian posterior distributions

1. INTRODUCTION

- ▶ Study, characteristics, probability distribution $f(\cdot)$
- ▶ If simple, analytically
- ▶ If complicated, numerical integration, issues, accuracy, stability, and scalability to higher dimensions
- ▶ Solution, Monte Carlo algorithms, estimate features, samples
- ▶ Example:
 - Estimate mean
- ▶ Solution:
 - With samples $x_t \sim f$, we can estimate the mean of $f(x)$ as $\hat{\mu} = \frac{1}{T} \sum_{t=1}^T x_t$

1. INTRODUCTION

- ▶ Key challenge, efficiently generate samples
- ▶ Univariate case, many, inverse cumulative distribution function algorithm is popular
- ▶ Arbitrary multivariate distributions, challenging
- ▶ Rejection sampling attempts to solve this problem
- ▶ Problem, how to select good $g(x)$ that is easy to sample from

1. INTRODUCTION

- ▶ Markov chain Monte Carlo algorithms
- ▶ Markov chain $\{x_t\}_{t=1}^T$, transition kernel $K(x_t | x_{t-1})$
- ▶ Samples $\{x_t\}$, converge, stationary distribution is target distribution
- ▶ Burn in, isn't stationary at the beginning
- ▶ Particularly popular in Bayesian inference

1. INTRODUCTION

- ▶ Metropolis, 1953, built on rejection sampling
- ▶ Samples candidate \tilde{x} from proposal density (symmetric)
- ▶ Set $x_t = \tilde{x}$ with probability $\alpha(\tilde{x} | x_{t-1}) = \min \left\{ 1, \frac{f(\tilde{x})}{f(x_{t-1})} \right\}$ and $x_t = x_{t-1}$ otherwise
- ▶ Big problem, only symmetric distributions

1. INTRODUCTION

- ▶ Hastings, 1970
- ▶ Improved, asymmetry
- ▶ Set $x_t = \tilde{x}$ with probability $\alpha(\tilde{x} | x_{t-1}) = \min \left\{ 1, \frac{f(\tilde{x})}{f(x_{t-1})} \cdot \frac{g(x_{t-1} | \tilde{x})}{g(\tilde{x} | x_{t-1})} \right\}$ and $x_t = x_{t-1}$ otherwise
- ▶ Most popular MCMC algorithm
- ▶ Most common approach to modern Bayesian computation

1. INTRODUCTION

- ▶ Top 10 most important algorithms of the 20th century
- ▶ Hydrogen bomb, "mathematical analyzer, numerical integrator, and computer"
- ▶ Didn't mention Bayesian statistics, but is most prominent today
- ▶ Made Bayesian statistics feasible

2.1. Overview

- ▶ How to choose a good proposal having high computational efficiency?
 - (i) Computational cost per iteration of the sampler
 - (ii) Mixing rate of the Markov chain $\{x_t\}$
- ▶ (i), dependent, cost of sampling, calculating acceptance probability
- ▶ (ii), samples are not independent, x_t and $x_{t+\Delta}$ are correlated
- ▶ Slow mixing, correlation between x_t and $x_{t+\Delta}$ decreases slowly, samples contribute less information
- ▶ Effective sample size

2. Extensions

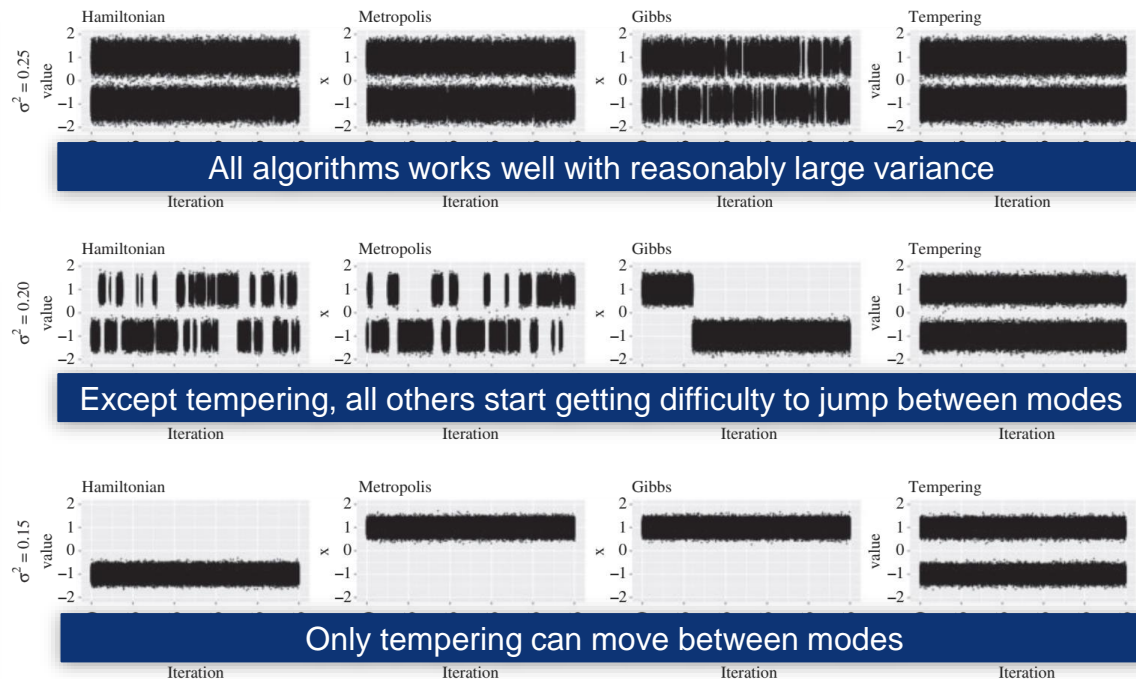

- ▶ Gibbs
- ▶ Metropolis-within-Gibbs
- ▶ Blocking
- ▶ Adaptive algorithms
- ▶ Gradient-based algorithms
 - ▶ Metropolis-adjusted Langevin
 - ▶ Hamiltonian Monte Carlo

3. Challenging – Multimodal targets

Solutions for multimodal:

- simulated
- **tempering**
- equi-energy sampler
- split–merge samplers
- birth–death algorithm

Hasting algorithm can **fail** to move among **modes** of the multimodal distribution.

3. Challenging – Intractable likelihoods

Example of intractable likelihoods:

- g-and-k distribution:

$$Q(u; A, B, g, k) = A + B \left[1 + c \frac{1 - \exp\{-g\Phi(u)\}}{1 + \exp\{-g\Phi(u)\}} \right] \{1 + \Phi(u)^2\}^k \Phi(u)$$

$$Q(u; A, B, g, k) = A + B \left[1 + c \frac{1 - \exp\{-g\Phi(u)\}}{1 + \exp\{-g\Phi(u)\}} \right] \{1 + \Phi(u)^2\}^k \Phi(u)$$

- Two-dimensional summary statistics:

$$x_1, \dots, x_n \stackrel{\text{iid}}{\sim} N(\theta, \sigma^2),$$

$$S(x_1, \dots, x_n) = (\text{med}(x_1, \dots, x_n), \text{mad}(x_1, \dots, x_n)),$$

Solutions for incomputable likelihoods:

- auxiliary variable scheme
- rejection sampling
- Pseudo-marginal Metropolis Hastings

=> We need unbiased estimate of the likelihood in the acceptance probability

Likelihood functions can be intractable, meaning it is **not computable** even up to a normalizing constant.

3. Challenging – Distributions with constrained support

Solution for constrained support distribution:

- ignore the constraint and simply reject proposals falling outside of C ;
- reparameterize to an unconstrained space before running the sampler
- Gibbs sampling with the conditional posterior distributions truncated to reflect the constraint

Hard to implement appropriate proposal distribution with the **same support**

Bonus: The effect of proposal selection in MCMC

Given a target distribution,

- What is the difference we select one proposal over another?
- Is there a “better” proposal distribution over some others?

Case 1: Target and proposal are both Gaussian

Target

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

Proposals

$\text{Cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

$\text{Cov} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$

$\text{Cov} = \begin{bmatrix} 1 & 0.9 \\ 0.9 & 1 \end{bmatrix}$

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0.9 \\ 0.9 & 1 \end{bmatrix}$

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0.9 \\ 0.9 & 1 \end{bmatrix}$

Case 1: Target and proposal are both Gaussian

Cov = $\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

Acceptance rate: 57%

Cov = $\begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$

Acceptance rate: 55%

Cov = $\begin{bmatrix} 1 & 0.9 \\ 0.9 & 1 \end{bmatrix}$

Acceptance rate: 58%

Case 2: Target is Gaussian, proposals are skew Gaussian

Target

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

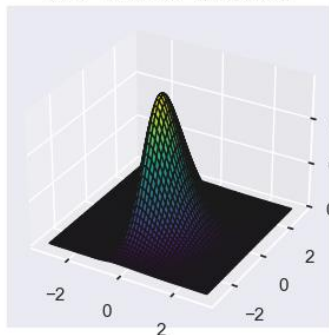

$\alpha = [0, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

Proposal

shape = [5, 0],
 $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

$\alpha = [5, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

$\alpha = [5, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$

shape = [5, 0],
 $\text{cov} = \begin{bmatrix} 1 & 0.9 \\ 0.9 & 1 \end{bmatrix}$

$\alpha = [5, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0.9 \\ 0.9 & 1 \end{bmatrix}$

$\alpha = [5, 0]$, $\text{cov} = \begin{bmatrix} 1 & 0.9 \\ 0.9 & 1 \end{bmatrix}$

shape = [5, 10],
 $\text{cov} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$

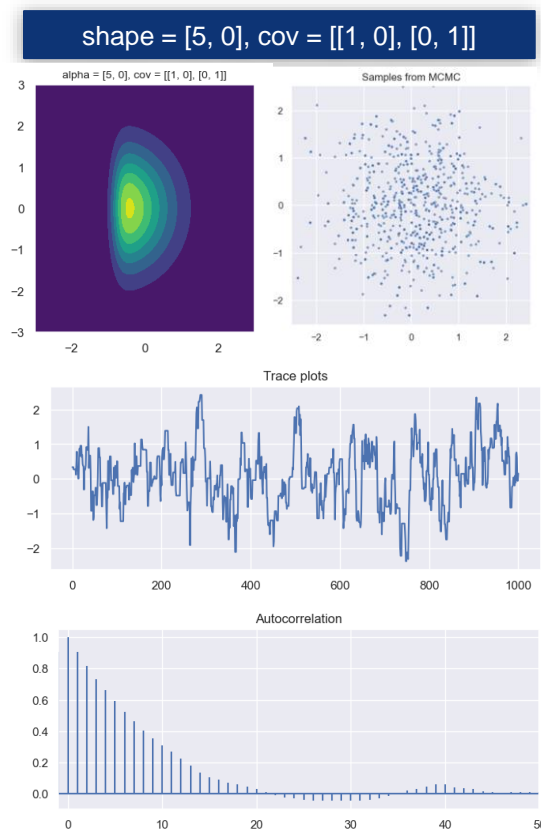

$\alpha = [5, 10]$, $\text{cov} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$

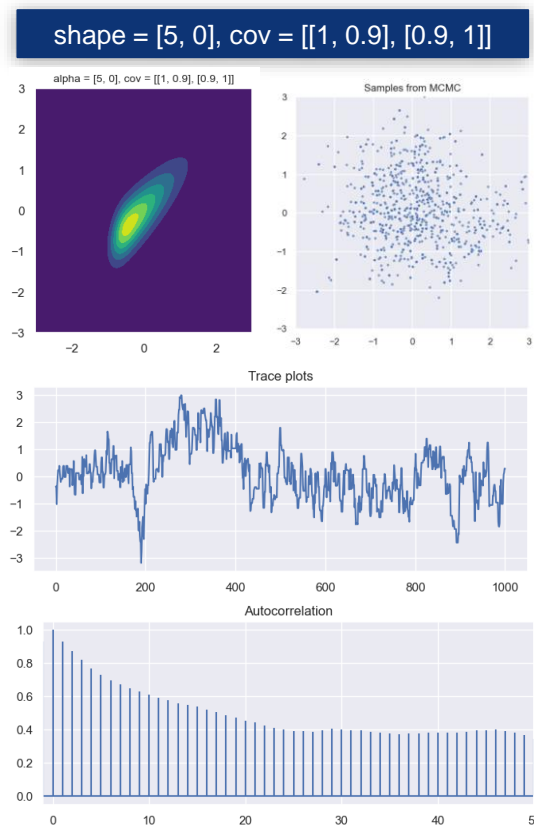

$\alpha = [5, 10]$, $\text{cov} = \begin{bmatrix} 1 & 0.5 \\ 0.5 & 1 \end{bmatrix}$

Case 2: Target is Gaussian, proposals are skew Gaussian

Acceptance rate: 56%

Acceptance rate: 62%

Acceptance rate: 56%

Case 3: Target is Gaussian, proposals are gama / log

Target

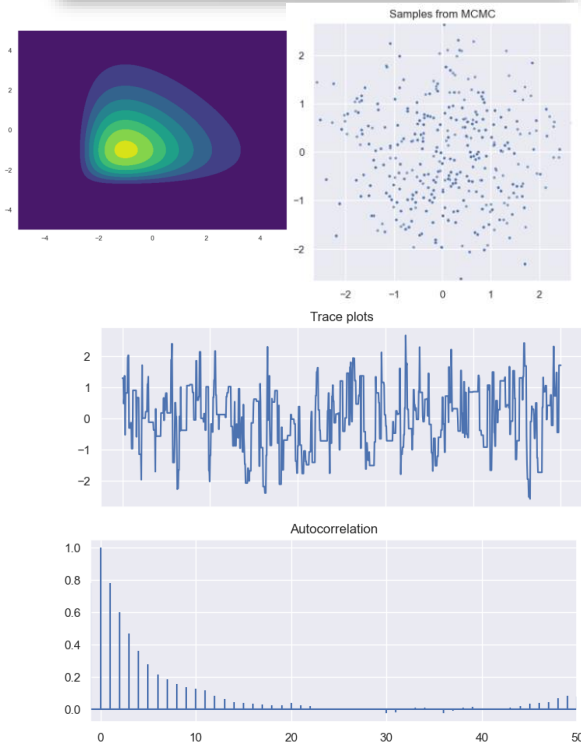

Proposal

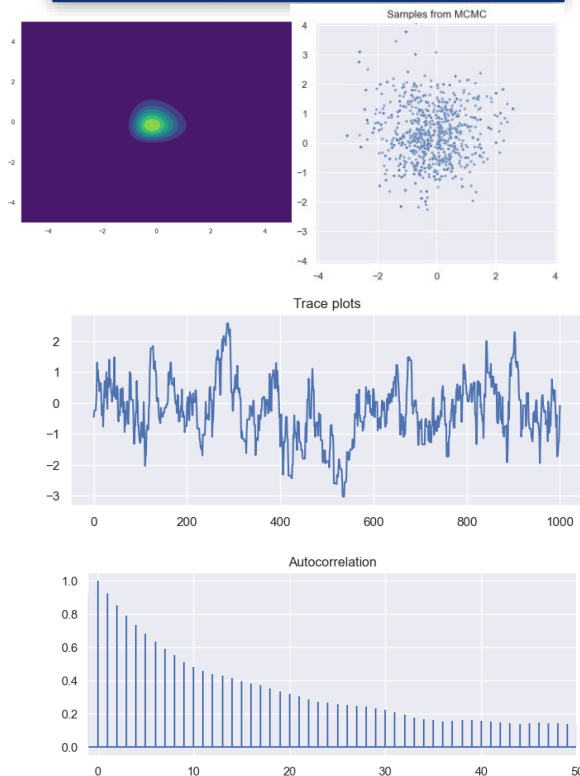

Case 3: Target is Gaussian, proposals are gama / log

Gama distribution

Acceptance rate: 37%

Lognormal distribution

Acceptance rate: 66%

Note that the support of gama and log normal are not the same as Gaussian.

But still, they give reasonable result.

The effect of proposal selection in MCMC

Given a target distribution,

- What is the difference we select one proposal over another?
-> It seems that the more “similar” to the target the proposal is, the better the samples are (in term of autocorrelation)
- Is there a “better” proposal distribution over some others?
-> Choose the best-knowledge proposal that is similar to target , i.e. the prior distribution?

Questions

1. Adaptive algorithms
2. What are some advantages of gradient-based algorithms compared to other MCMC methods?
3. What is the best proposal distribution? Should we choose the one that is similar to prior distribution?
